Abstract

Job satisfaction simply means the employee's feeling of fulfillment from their job. Wanting to change current jobs could be one of the measures to measure job satisfaction and dissatisfaction. This paper's main objective is to determine whether receiving cash remuneration alongside other services like transportation, uniform, and others have a relationship with job satisfaction or not. Using the logistic regression and marginal effect to check the influence on the dependent variable which is job satisfaction but not the causal relationship, Nepal Labour Force Survey 2017- 2018 third round survey data is used. The overall result supports my hypothesis that received cash remuneration, uniform facility, and transportation facility have shown a significant relationship with job satisfaction. Where received cash has shown positive relation to wanting to change current jobs which means it is negatively related to job satisfaction and uniform and transportation facilities have shown negative relation to wanting to change the current job which means they are positively related to job satisfaction. Following Herz-berg's two factor-theory, the cash remuneration variable aligns with the theory. This paper also makes some recommendations for policies and counterarguments for Nepal which can help to enhance the positive relation also giving priority to the intrinsic factors.

Introduction

In an era of heightened competition for top talents, understanding the factors contributing to employee job satisfaction has become a pressing concern for many organizations seeking to attract and retain the best employees. In the current time of fierce competition, it is essential for a business to have a workforce that is committed to reaching its goals and can function well as a team. The corporate environment is changing quickly, and there is an increasing need for high-quality goods and services. A sense of commitment and loyalty among workers should be fostered by firms just as much as employing skilled individuals is. Employee performance and contribution to business success are only possible when they are fully devoted to their jobs and the organization. Building a devoted staff is therefore essential for firms hoping to maintain their competitiveness in the rapidly evolving business landscape of today.

Employees are essential to achieving the enterprise's objective and vision in the production domain. Employees are required to achieve the performance standards set by the business in order to guarantee the quantity and quality of their work. Employees need a workplace that allows them to work without any obstacles that can limit their productivity or potential, nevertheless, in order to live up to these requirements (Raziq & Maulabakhsh, 2015, 717-725). (Pradhan, 2020, 255-264) Similarly, an employee's degree of dedication is a key indicator of both their success and turnover. Organizations that value their employees and want to keep high-performing staff should thus concentrate on raising their level of commitment.

(Dziuba et al., 2020, 18-25) Likewise, employees need a supportive superior who can inspire them to perform productively and feel content with their employment in addition to a pleasant work environment. Such a manager must not only create the ideal environment for employees to succeed but also inspire and motivate them to carry out their duties ethically. (Abuhashesh et

al., 2019, 23) Job satisfaction differs from person to person as it is a subjective indicator. Numerous variables, including management style, income, working conditions, schedule, perks, stress levels, and flexibility, might have an impact. Being connected to productivity, motivation, work performance, and general life happiness, job satisfaction has important effects outside of the office. To enhance the quality of employees' lives both at work and outside of it, it is crucial to consider the complex nature of job satisfaction.

(Wolniak & Olkiewicz, 2019, 10-17) The sense of security that employees feel within the company is significantly influenced by their level of job satisfaction. When workers are happy in their positions, they not only feel better about their work but also more secure about their futures inside the company. As a result, job satisfaction is crucial to maintaining workplace safety and needs to be seen as a crucial component of employee wellbeing.

Statement of the Problem and Research Question

(Pradhan, 2020, 255-264) Interest in the field of employee commitment, remuneration management, and job satisfaction is expanding in modern times. This is so that organizations may achieve their goal since workers are the most important and valuable resources in any business. Additionally, guaranteeing their loyalty to the company and job satisfaction is essential. Employees may be encouraged to perform at their highest level in a number of ways, including bonuses and services provided by employers. Employees are often employed by the employer based on their ability, productivity, skill, knowledge, and experience and they are paid in a variety of ways including wages, salaries, bonuses, commissions, and other extra services. However, people with strong educational backgrounds tend to be demotivated when their job does not support their future career development. Additionally, the services and bonuses they

provide do not match their educational qualifications. This often leads to dissatisfaction and wanting to change their current job.

Likewise, a growing number of people are interested in employee bonuses and services. More and more leading companies and workplaces provide their employees with health insurance, discounts at stores, free transportation, and monetary bonuses as perks to keep their employees satisfied. This alongside a number of contextual elements, including the working environment, company culture, and remuneration, has been identified in the literature as having an influence on job satisfaction. Every sector, which depends on trained staff to fulfill the demands of new technologies and shifting consumer expectations, is one of many firms whose top concern in today's fiercely competitive business climate is employee job satisfaction. Organizations might incur costs and lose market share as a result of high personnel turnover rates and retention issues. Therefore, it has become a top concern for many firms to comprehend the elements that impact work satisfaction and develop solutions to improve it.

(Silwal, 2021) According to research, both monetary rewards and non-monetary ones, such as those connected to fringe benefits, may have a favorable effect on work satisfaction. In the end, a variety of factors, such as personal preference, coworkers, job security, and supervisors, have an impact on one's desire to feel connected to their workplace, underlining the complexity of job satisfaction.

Likewise, the challenges faced by organizations and employers include absenteeism, performance gap, and trouble keeping qualified staff. Numerous governmental and commercial firms in Nepal have failed, and ineffective management has been cited as a major factor in these failures. Although the issues with low work satisfaction have been identified and studied, not much has been done to resolve the problem and prevent employee dissatisfaction. Since

bonuses and services are thought to play a significant role in determining job satisfaction, it is crucial to comprehend their significance in this situation. Hence, this research would like to shed light upon some factors that affect job satisfaction outside of just salary in Nepal and how much job perks are affecting the workforce in Nepal with their likelihood to stick with their employers.

Likewise, the research question is “Can additional services and bonuses by employers like cash remuneration to employees affect job satisfaction and to what degree do they affect?”

And its objective is to determine the factors influencing job satisfaction among workers and their relative importance with a focus on understanding the reasons for job satisfaction or dissatisfaction.

Furthermore, its Hypothesis:

H0: There is no relation between the services and bonuses employers provide and job satisfaction.

H1: There is a relation between the services and bonuses employers provide and job satisfaction.

Literature Review

(Konopaske et al., 2011) Job satisfaction is the degree to which people are happy with their jobs and the tasks they complete which in turn influences their general feeling of well-being. Positive feelings and actions, such as good attendance, low turnover rates, better productivity, more engagement, and higher customer satisfaction, are more common among workers who have high levels of job satisfaction.

Similarly, higher work satisfaction, in accordance with (Sarwar S. & Abugre J., 2017, 289-298), promotes employee engagement and loyalty to their employer. In contrast, poor remuneration and insufficient incentives can contribute to work dissatisfaction. Managers in the public sector, according to Chew (2005) and Pare and Trembley (2007), were more focused on maintaining their jobs than receiving financial compensation.

A number of elements that go together to create a sense of fulfillment are referred to as job satisfaction. It is an emotional condition of joy brought on by the assessment that one's work according to Locke's 1969 definition (Locke & A., 1969, 309-336) supports or fulfills one's ideals and aims. Similarly to this, (Meier & Spector, 2015) describes work satisfaction as a person's attitude toward different elements of their employment, whether they are favorable or bad.

Similarly, according to (Robbins & Judge, 2016), there are five main factors that contribute to job satisfaction, coworkers, income, careers, and the job itself. A business must make sure that its personnel are happy with their jobs. According to studies by (Caesens & Stinglhamber, 2014, 259-267), satisfied workers are more likely to be engaged (Lambert et al., 2015, 1-22), committed to the organization, stay with the company longer demonstrate strong organizational citizenship behavior), and perform better.

Similarly, on paper titled “Reward and Job Satisfaction: An Evidence from Private Colleges of Nepal” (Adhikari, 2023, 178-190) states that (Mumford, 1972), quoted in (Buitendach & Witte, 2005) and (Sempene et al., 2002) classified the most frequent components of job satisfaction as work, promotion, recognition, benefits, working conditions, supervision, coworkers, company, and management. Similarly to this, (Hunt et al., 2019) stated that a favorable working environment, helpful coworkers, cognitively demanding work, equitable incentives, supportive working conditions, and a strong personality-job fit all contribute to job satisfaction.

Additionally, he stated that Spector (2000) also suggested organizational structure as a potential source of unhappiness, whereas status and work content were listed as potential factors for job satisfaction. (Mumford, 1972) emphasized that the fit between a person's preferences and what they receive, as well as the alignment between what the employer expects and what the employee wants, are used to measure work happiness. Employee fulfillment is a result of a variety of advantages rather than a single incentive, as multiple authors have noted (Farnsworth et al., 2002).

(Adhikari, 2023, 178-190)The main goal of rewarding employees is to encourage positive conduct while discouraging undesirable behavior that can compromise company productivity and efficiency. There are several methods to reward employees depending on the type of job they do, even while incentives like wages and salaries are offered as a recompense for work. There are two types of rewards: intrinsic and extrinsic. Also, he mentions, managers can use concrete external variables known as extrinsic incentives to motivate workers to increase their productivity. These incentives might come in the form of cash, benefits, flexible work hours, promotions, new duties, praise and feedback from management, and organizational culture.

Likewise, In (Urooj et al., 2013) paper, the results of the study showed that the element having the greatest influence on teachers' satisfaction with their jobs was their remuneration, while the factor with the least significant impact was their coworkers. Most teachers stated that if they were given a greater wage and better fringe benefits, they would be happier in their jobs. The study also came to the conclusion that the instructors' substandard pay had a detrimental impact on how well they taught.

Furthermore, (Luddy, 2005) According to a survey done in a public health facility in the Western Cape, staff in that facility was most content with their coworkers, followed by the nature of their jobs and their level of supervision. They did, however, express lower levels of satisfaction with possibilities for promotion and the lowest levels of happiness with their salary.

However, (Hakuduwal, 2021) claimed that a number of things have a big impact on how satisfied staff are with their jobs. Job satisfaction is reported to be positively impacted by pay and benefits, the workplace, career advancement, and job stability, but negatively impacted by coworker relationships. The survey also discovered that job security, followed by remuneration and rewards, the working environment, and career growth chances, has the most beneficial impact on employee job satisfaction.

Furthermore, the (Sukdeo, 2017) study's findings demonstrated that elements including fair treatment, excellent compensation, comfortable working conditions, job security, and training chances all contributed to the high level of job satisfaction among employees. Because they felt at home and enjoyed working there, employees reported feeling more satisfied with their jobs and producing more. So, it is essential to maintain high levels of employee satisfaction if you want your firm to succeed overall.

Similarly, according to (Silwal, 2021) study, it was shown that intrinsic incentives, such as job autonomy, task relevance, recognition, and job satisfaction are significantly correlated in both banks. This shows that these kinds of incentives help create a highly pleased workforce. The study also examined the relationship between extrinsic rewards and work satisfaction and discovered that the outcomes across the two banks varied. Employees at Himalayan Bank concurred that job happiness is influenced by extrinsic rewards. This suggests that employees in private companies are happier receiving extrinsic rewards than intrinsic ones.

Furthermore, (Pouliakas, 2008) The results of this study provide evidence for the V-shaped relationship between financial incentives and employee performance and job satisfaction. To put it another way, there is a discontinuity at zero payment, and above-average compensation, particularly significant bonuses, and profit-sharing payments can increase work satisfaction. Even after accounting for the impact of additional variables that could have an impact on the connection between incentives and work satisfaction, these findings persisted. Their research contends that an employee's total job satisfaction is influenced by variables other than pay and effort.

(Pradhan, 2020, 255- 256) In conclusion, the study showed that employee commitment in service sector businesses is positively impacted by both remuneration structures and work designs.

Additionally (Tripathi et al., 2020, 88-93) study indicated that job satisfaction was impacted by elements including sex, working post level, remuneration, training chances, promotion, and decision-making role and that 66% of PHC-level health professionals reported being happy with their jobs. Responsible entities should take into account these aspects and offer possibilities for

training, promotion, higher pay, and pensions to boost job satisfaction among healthcare professionals in order to improve healthcare services.

According to (Khadka, 2013) research on job satisfaction in Nepal's banking sector, 79.1% of employees were happy with their present pay. The majority of workers were also pleased with the procedures used for hiring new personnel, leaving on leave, and receiving bonuses. The majority of employees concurred that there is no nepotism in the bank's selection process and that the correct individual is chosen at the appropriate time and location. Additionally, the majority of workers expressed satisfaction with their employment responsibilities.

Theoretical Model

Herzberg's (Giroux, 1960, 275-276) Two-Factor Theory was one of the first ideas to describe human wants (Ramlall, 2004, 52-63). People, according to Herzberg, have two distinctive types of needs: hygienic factors (external factors) and motivators (interior factors). Herzberg discovered that satisfaction and dissatisfaction are discrete ideas impacted by diverse causes, rather than being opposing extremes of a single spectrum (Baylor, 2010), in research involving 200 accountants and engineers in Pittsburgh. As different models (Brockman, 1971, 155-189) demonstrate, this viewpoint contradicted typical thinking at the time. Herzberg's theory of motivation followed Maslow's (1943) views by acknowledging that personal growth influences motivation, particularly when learning leads to individual achievement. This emphasis on self-development is critical for firms to attain long-term commercial goals.

As mentioned earlier, the two-factor theory is similar to Maslow's hierarchy of needs, but it incorporates extra aspects to assess workplace motivation. According to this idea, satisfying lower-level demands, known as extrinsic or hygiene aspects, would not encourage individuals to

invest effort but will just avoid dissatisfaction. Likewise, higher-level wants, known as intrinsic or motivation aspects, must be met in order to effectively motivate employees. According to this theory, addressing extrinsic or hygienic considerations would merely keep employees from becoming actively unhappy/dissatisfied, but will not motivate them to put in extra effort for greater performance. Hence, organizations should focus on meeting intrinsic or motivational aspects to encourage employees (Robbins & Judge, 2009).

Now talking about extrinsic factors, also known as employment context factors, contribute to the creation of a pleasant working atmosphere in which they feel at ease. They are external satisfactions offered by others with the goal of avoiding uncomfortable working conditions and job dissatisfaction. Furthermore, according to the theory, intrinsic and extrinsic elements are interrelated. Extrinsic elements simply reduce job dissatisfaction and they do not offer job satisfaction. In contrast, an adequate supply of intrinsic elements, fosters employees' inner growth and development, resulting in increased productivity and performance. In the absence of intrinsic elements, the employees are neither satisfied nor dissatisfied. Employees' propensity to work is enabled by extrinsic variables, whilst intrinsic elements dictate the quality of their job. These two groupings of characteristics are not always diametrically opposed but rather indicate various levels of satisfaction and dissatisfaction (Robbins & Judge, 2009).

In this paper, for example, I looked at the services and bonuses that businesses provide to their employees, such as cash remuneration, residence facility, food/beverage facility, transportation facility, and uniform facilities. These variables, according to the theory, are classified under hygienic or extrinsic factors. It is vital to highlight that these services and bonuses do not immediately contribute to employees' job satisfaction. Instead, their primary function is to prevent employees from becoming dissatisfied with their job.

Data and Estimation Methodology

In this part, I will provide a detailed review of the factors that will be used in this study to determine their relationship with job satisfaction. In addition, I will discuss the tactics I will use to manage the raw data, such as variable categorization into sub-observations and the treatment of any missing values.

Methodology

For the empirical specification, I will be using Logistic regression. My dependent variable is wanting to change their current job which is inversely related to job satisfaction. Wanting to change current job has possible two outcomes. Yes or No. Hence, I will be using logistic regression to analyze the connections between binary dependent variables with one or more independent variables. The independent variable in my research is services and bonuses provided by employers which are received as cash remuneration for the main job, residence facility, food/ beverage facility, transportation facility, and uniform. Furthermore, control variables that I have taken into consideration are the working age population (15-64), individuals working in the agriculture sector or not, their education level, and finally their involvement status in the job. I will also be incorporating clustering standard error using psu which is the primary sampling unit.

For this kind of study, logistic regression would be an appropriate choice since it can calculate the likelihood of a certain result (in my paper, job satisfaction) depending on the values of the independent variables. A binary response variable, with a response of either 0 or 1, is modeled using it. Based on the values of the independent variables, the binary logistic regression model predicts the likelihood that the outcome variable will be 1.

I will also use the marginal effect on each of the independent variables in both models to quantify the probability of changes in the outcome. In my case the change in “wanting to change one’s job” when the independent factors, for example, the cash remuneration for the main job changes and to what degree it affects the dependent variable.

Empirical Strategy

Model1

$$\text{Logit}(p) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \beta_6 X_6 + \beta_7 X_7 + \beta_9 X_9 + \beta_{10} X_{10} + \beta_{11} X_{11} + e$$

Model2

$$\text{Logit}(p) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \beta_6 X_6 + \beta_7 X_7 + \beta_8 X_8 + e$$

p = probability of the dependent variable is equal to 1 (wants to change current job)

β_0 = intercept term

β_1 = received cash remuneration of the main job

β_2 = residence facility

β_3 = food/ beverage facility

β_4 = transportation facility

β_5 = other than the uniform facility

β_6 = working age population (15-64)

β_7 = working in the agriculture sector or not

β_8 = Primary education

β_9 = Secondary education

β_{10} = Intermediate and higher education

β_{11} = employee

X_1 - X_{11} = are the values of the independent variables for each observation

e = error term

Here, job satisfaction is my dependent variable. The independent variables are received cash remuneration of the main job, residence facility, food/beverage facility, and transportation facility, other than the uniform facility. Talking about the control variables, are the working-age population, education level, involvement status in the job, and working in the agriculture sector or not. Although these variables are not the main focus of the study, keeping their values allows it to discover the true connection between job satisfaction and received cash remuneration and other services. Because these variables influence the job satisfaction of an employee directly or indirectly.

Data and sources

I will be using the Nepal Labour Force Survey 2017-2018, Third Round. It is the survey data that was collected by the Central Bureau of Statistics (CBS). Now talking about the data, and the Sampling procedure, a total of 18,000 homes were chosen for this study, with 10,500 coming from urban regions and 7,500 coming from rural ones. Probability Proportional to Size (PPS), a two-stage approach, was employed in the selection process. Wards were selected for the first stage based on their size, which was established by the number of households counted during the census. Then, all of the homes in the specified ward (or sub-ward, or combination of tiny wards) were identified, and 20 households were picked using systematic sampling. Also, the survey included 168 questions in 14 sections. Furthermore, the unit of my analysis is an

individual household with 78,496 observations. I will focus on the working-age population, which is defined as those between the ages of 15 and 60.

Table 1: Descriptive Statistics

Variables	Definition	Observation	Mean	SD	Min	Max
Independent Variable:						
Job Satisfaction						
change job	Want to change current work/job (Yes=1/No=0)	16,034	.2017839	.4013443	0	1
Independent Variables:						
Services & Bonuses						
rcvd_cash	Receive cash remuneration of the main job (Yes=1/No=0)	47,561	.1798743	.3840867	0	1
faci_resid	Residence facility received from an employer (Yes=1/No=0)	47,561	.0080738	.089492	0	1
faci_food bev	Food/beverage received from an employer (Yes=1/No=0)	47,561	.0177877	.1321804	0	1
faci_dress	Transportation facility received from an employer (Yes=1/No=0)	47,561	.0051092	.0712968	0	1
faci_trans	Uniform received from an employer (Yes=1/No=0)	47,561	.0175564	.1313337	0	1
Control Variables						
age	Working age population (15-64)	47,574	34.3034	13.85377	15	64
new_wrk_agri_sect	Is this work in the agriculture sector (Yes=1/No=0)	47,561	0.636446	0.2441213	0	1

primary_education	Nursery, LKG/UKG, grades 1,2,3,4, and 5, literate, and illiterate (Yes=1/No=0)	47,561	0.46925	0.4990588	0	1
secondary_education	Grades 6,7,8,9, and 10, and a professional degree (Yes=1/No=0)	47,561	0.2872101	0.4524652	0	1
Intermediate_level_or_higher	SLC & equivalent, +2 & intermediate, Bachelor level & equivalent, master level & above (Yes=1/No=0)	47,561	0.2435399	0.4292226	0	1
employee	Employee, paid apprenticeship/ intern (Yes=1/No=0)	16,218	0.5276236	0.4992517	0	1

The descriptive statistics and variable descriptions are shown in Table 1. It provides definitions, the number of observations, the mean, the standard deviation, and the minimum and maximum values. Before cleaning, the raw data consisted of 78,496 observations. Following data cleaning and file merging for the specified variables, a total of 49,940 observations remained.

Similarly, I used the questionnaire to deal with null values. The null values for variables such as employment services and bonuses, cash remuneration, residence facility, food/beverage facility, transportation facility, and uniform facilities were recorded as No with a STATA code of 2. Similarly, the null values for the variable indicating whether the job was in the agriculture sector or not were similarly tagged as No with a STATA code of 2. Moving on to the employee's highest degree of education, null values were classified as illiterate owing to a negative response. Since an uneducated person is considered illiterate, the null values were assigned to the Illiterate category using a STATA code of 17.

Let us now look at the control variables, indicating whether or not someone works in agriculture is binary, having two outcomes: yes or no. The original coding used 1 to indicate yes and 2 to indicate no. The values were re-coded as 1 for yes and 0 for no.

Similarly, I only included the working age group, which extends from 15 to 64, for additional control variables such as age.

The variable representing the highest education level attended contained 17 observations, which I classified into three groups: primary, secondary, and intermediate or higher education levels. Nursery, LKG/UGK, grades 1–5, literate, and illiterate were all included in primary education. As shown in Table 1, I included grades 6 to 10, as well as professional degrees in secondary level education and SLC & equivalent, +2 & intermediate, Bachelor level & equivalent, and master level & above, in the intermediate or higher education level group. After classifying these variables, I constructed separate dummy variables with yes representing 1 and no representing 0.

Let us now look at the involvement status in a job variable that had six different observations. I opted to delete the sixth category due to a low amount of observations, leaving five categories. I divided them into two categories: employee and employer. But I have taken employee variables into consideration for this research. Regular employees and paid apprentices/interns were included in the employee group. Similarly, I established separate dummy variables for these variables and assigned a value of 1 for yes and 0 for no.

Empirical Findings

I have created two logistics regression models.

Model 1 includes the dependent variable job satisfaction which is measured by changing jobs and my independent variables as received cash remuneration, residence facility, food/beverage facility, transportation facility, and uniform facility. For the control variable, this model has worked in the agriculture sector or not, secondary education level, intermediate education level, and employee.

Model 2 includes the dependent variable job satisfaction which is measured by changing jobs and my independent variables as received cash remuneration, residence facility, food/beverage facility, transportation facility, and uniform facility. For the control variables, this model has worked in the agriculture sector or not, and primary education level. I have included primary education in this model because it is my baseline variable which I will be using for comparison purposes.

Employing these two logistic regression models to analyze the influence of numerous factors on job satisfaction, especially the employer's facilities. The models will assist me in analyzing the association between these variables and job satisfaction while accounting for the control variables that may impact the results.

Table 2: Logistic Regression Result

	Model 1	Model 2
VARIABLES	Change job	Change job
Received cash remuneration	11.82*** (0.694)	0.939*** (0.0604)
Residence facility	-0.289 (0.200)	-0.290 (0.200)
Food/Beverage facility	0.122 (0.116)	0.125 (0.116)
Transportation facility	-0.517** (0.225)	-0.525** (0.225)
Uniform facility	-1.577*** (0.147)	-1.588*** (0.146)
Work in agriculture sector or not	0.179** (0.0844)	0.182** (0.0844)
Secondary education	0.406*** (0.0593)	
Intermediate level or higher	0.367*** (0.0641)	
Employee	-10.88*** (0.706)	
Primary education		-0.386*** (0.0547)
Constant	-2.109*** (0.0668)	-1.723*** (0.0588)
Observations	16,032	16,032

Robust standard errors in parentheses

*** p<0.01, ** p<0.05, * p<0.1

In the above-shown Table 2 result, received cash remuneration is positively significant to the wanting to change current job in both models. Similarly, the result for the transportation facility and the uniform facility is also significant but negative to want to change the current job in both models 1 and 2. Whereas the result for residence facility and food/beverage facility are insignificant to wanting to change current job in both models.

Talking about the main variable of interest, which is received cash remuneration, is positively significant with a changing job, which means negatively significant to job satisfaction. In both models 1 and 2, the values show that for a one-unit increase in the cash remuneration facility given to employees, we expect an 11.82 and 0.939 increase in the log-odds of wanting to change current job which is a decrease in job satisfaction.

Likewise, for the transportation and uniform facility, their values are negatively significant with wanting to change their current job, which means it is positively significant with job satisfaction. The values for transportation facilities show that for a one-unit increase in the facility, we expect a 0.517 and 0.525 decrease in log odds of wanting to change current jobs which means this variable is positively affecting job satisfaction in models 1 and 2. For uniform facility, a one-unit increase in the facility, we expect a 1.577 and 1.588 decrease in log-odds of wanting to change current jobs which means this variable has a positive relation to job satisfaction in models 1 and 2.

Now moving on to the control variables, who is working in the agriculture sector or not is positively related to wanting to change jobs but negatively to job satisfaction. As per the result, if there is a unit rise in people engaging in the agriculture sector then people's tendency to change jobs increases by log odds of 0.179 in model 1 and 0.182 in model 2. Likewise, moving onto the education level, both secondary and intermediate or higher level education levels are positively significant to change jobs hence, negative to job satisfaction in model 1. This means if an employee's education level is among these two their tendency to change jobs increases by log odds of 0.406 and 0.367 respectively. Whereas, for primary education in model 2, which is negatively significant with wanting to change current job. So this means if an employee's

education level is primary education then their tendency to change jobs decreases by log odds of 0.386, leading to positive significance with job satisfaction.

Comparing both results, there have not been any drastic changes in the results besides for received cash remuneration. In both models residence facilities and food/beverage facilities are insignificant. The trend we see comparing the regression results from Model 1 and Model 2 is that across the board the tendency to change jobs slightly increases in every variable except for received cash remuneration. Meaning if there was a positive or negative relation found the relation becomes a little stronger for example, in transportation facilities, the log odds increase from -0.517 to -0.525, from model 1 to model 2. Similarly, for a uniform facility, the negative relation has become slightly stronger in model 2 compared to model 1. The values go from -1.577 to -1.588.

However, for received cash the values are positive in models 1 and 2. But the relation model 1 is much stronger than model 2 with change job, as the value for model 1 is 11.82 and model 2 is 0.939.

Table 3: Marginal Effect result

	Model 1	Model 2
VARIABLES	Change job	Change job

Standard errors in parentheses

*** p<0.01, ** p<0.05, * p<0.1

The marginal effect of cash remuneration is 1.828 and 0.145 for model 1 and model 2 respectively which are both significant and means when all other variables are kept constant and if one individual's cash remuneration increases by 1, the probability of wanting to change jobs increases by 182.8 and 14.5 percentage points respectively. Meaning job satisfaction decreases by 182.8 and 14.5 percentage points respectively. This also means that the relationship becomes majorly weaker in Model 2. Hence, cash received has an influence on job satisfaction.

Similarly, the marginal effect for the provision of housing is -0.0447 and -0.0449 for models 1 and 2 respectively which are not significant to job satisfaction. Hence, statistically, there is no significant relation/ influence of residence facility on job satisfaction.

Moving on to the provision of food and beverages, there is a positive marginal effect of 0.0189 and 0.0193 in models 1 and 2 respectively but are not significant. Thus, theory does not have an influence on job satisfaction.

On to the fourth individual variable which is Transportation facilities, the marginal effect is -0.0799 and -0.0812 for Model 1 and 2 respectively, which are negatively significant with wanting to change your current job and positively significant to job satisfaction. This means when every other factor is kept constant and if the transportation facility is increased by 1 for an individual, the probability of wanting to change jobs decreases by -7.99% and -8.12% respectively. This signifies that the probability of job satisfaction increases by 7.99% and 8.12% respectively. Comparing both models, the relationship to job satisfaction is stronger in Model 2 slightly.

The uniform facility is our fifth independent variable with a marginal effect of -0.244 and -0.246 for Model 1 and Model 2 respectively which are significant to wanting to change current job and positively significant to job satisfaction. This means when every other factor is kept constant and if a uniform facility is increased by 1 for one individual, the probability of wanting to change jobs decreases by 24.4% and 24.6% respectively. This means that the probability of job satisfaction has increased by 24.4% and 24.6% respectively. Hence, the uniform facility has a meaningful impact on job satisfaction and while comparing both models, model 2 is slightly stronger.

Overall, received cash remuneration has a greater positive influence on wanting to change current job and a negative influence on job satisfaction in both models 1 and 2. Whereas, the uniform facility has a greater negative influence on wanting to change current job but a positive influence on job satisfaction in models 1 and 2 respectively. Following the trend of logistic regression, cash remuneration, and uniform facility are the most influencing factors for job satisfaction.

Discussion and Policy Recommendations

In contrast to our hypothesis and research question, there is a significant relationship between receiving cash remuneration, transportation facility, and uniform facility with wanting to change the current job. Surprisingly, only received cash remuneration has a positive and significant relationship associated with wanting to change current job, but it is negatively correlated with overall job satisfaction. Transportation and uniform facilities, on the other hand, showed a negative and significant link with the intention to change occupations, showing a positive relationship with job satisfaction.

Likewise, working in the agriculture sector or not, secondary level education and intermediate and higher level education also have a positive relationship with wanting to change the current job but have a negative relationship with job satisfaction. However, employee and primary education level have a negative relation with wanting to change their current job which indicates a positive relation with job satisfaction.

The result is presented in Table 2 with two different models. It showed that receiving cash remuneration and wanting to change jobs have and positive relation, which is significant. This means that cash remuneration and job satisfaction have a negative and significant relationship.

The results contradict the findings of (Gelard & Rezaei, 2016) and (Abbas et al., 2023, 177-181) revealing that the result shows a positive relation between job satisfaction and compensation satisfaction like cash remuneration. Now, why is there a strong positive relationship between cash received and wanting to change current job in this research paper which also can be written as a strong negative relationship between cash received and job satisfaction.

One possible explanation for the findings could be the influence of perceived justice and fairness in remuneration. Employees who think their monetary compensation is not proportional to their contributions, talents, or market rates may be dissatisfied with their jobs. Employees may voice their dissatisfaction in such instances by expressing a wish to explore new career possibilities. Thus, the positive link between monetary wage and wanting to change current jobs may imply that some people consider their salary to be inadequate, leading to a desire to seek better-paying opportunities elsewhere. Another reason for this result could be the data itself too. Because the outcome/observation of this cash remuneration variable was skewed towards no more which might lead to this result too.

Additionally, aligning with Herzberg's two-factor theory cash remuneration lies under the hygiene factor which does not particularly contribute to the worker's job satisfaction. Other intrinsic factors are needed to push the satisfaction factor.

Given the limited association between monetary pay and job happiness, managers, and employers should consider other aspects such as benefits satisfaction, contentment with wage increments, and work performance when developing ways to improve employee job satisfaction. This is especially true in a developing country like Nepal which is suffering from young workers preferring to go abroad for employment. Furthermore, researchers should be aware of the dataset's and study design's limitations, as well as the generalizability of their findings to diverse contexts.

Moving on to the food/beverage and residence facility which has insignificant relation to wanting to change current jobs. For the reasoning pointing out the data of food/beverage and residence facilities where most of the observations are skewed on the no response. We can assume that because of this the result might have been impacted. Also again connecting to Herzberg's theory, food/beverage and residence facilities fall under the hygiene factor which does not necessarily enhance job satisfaction among employees. Connecting to the theory, my result aligns which shows that working people of Nepal who are employees' job satisfaction is not quite affected by the food/beverage and residence facilities.

However, the provision of transportation and uniform facilities to employers also showed a positive relationship with job satisfaction as there is a negative relationship with wanting to change the current job. This result is backed by a study that came to the same conclusion. (Nelson & Bowen, 2000, 86-95) concluded that uniform features, design, comfort, and fit to their jobs were important to job satisfaction and had a strong positive relationship with job satisfaction.

The research findings emphasize the significance of addressing job satisfaction as a crucial factor in employee retention and organizational success. To foster a motivated and engaged workforce in Nepal, to begin a well-thought-out compensation and incentive strategy should be implemented. Like providing equal and competitive remuneration based on employees' contributions and performance. Furthermore, investigating facilities and developing a supportive work environment, such as transportation help, proper attire or dress code, and well-maintained workspaces, can improve job satisfaction levels. For example, workers from a few private organizations and government sectors such as police and armies are provided with the uniform. Providing the uniform gives a sense of belongingness to work for the employees. This might

enhance employees' satisfaction with his/her work. So providing uniforms or a dress code could help employees to be more connected to their job and creates a barrier to feeling dissatisfied with the job.

Similarly, employees should be able to communicate their opinions and concerns through open transparent communication channels allowing for continued growth. Likewise, employee development and training programs that provide possibilities for skill upgrading and career progression should be prioritized. Furthermore, encouraging work-life balance, recognizing employee accomplishments, and cultivating an inclusive workplace culture is critical for increasing job satisfaction and retention rates. Employee engagement surveys and departure interviews on a regular basis can assist gauge work satisfaction and suggest areas for focused improvements. These long-term evidence-based strategies can considerably improve worker satisfaction, resulting in a more motivated and engaged workforce in Nepal.

Conclusion

Job satisfaction plays an important role while determining a worker's productivity. Job satisfaction is crucial for Nepalese people since it has many implications for individuals, companies, and societies as a whole. Simply put together, job satisfaction is directly related to overall well-being and quality of life. Individuals who are happy with their employment report higher levels of happiness, contentment, and overall life satisfaction. This improves their mental and emotional well-being, resulting in a higher overall quality of life. Secondly, employees who are satisfied with their job are more likely to be motivated, engaged, and devoted to their jobs. This helps them become more productive, and commit to accomplishing the company's goal. Hence, this benefits both workers and employers in the long run with better performance and productivity.

Furthermore, it is important for lowering turnover rates, promoting loyalty, and fostering engagement. It is directly related to positive workplace connections and a healthy corporate culture, because pleased individuals have better interactions with their coworkers and superiors, resulting in a more peaceful work environment. Organizations that promote work satisfaction have a more pleasant and supportive culture, which contributes to employee well-being and overall organizational performance. Job happiness has larger societal and economic repercussions since it enhances productivity, productivity, professional growth, skill acquisition, and innovation within their respective sectors.

The objective of this paper was to determine the factors influencing job satisfaction among workers and their relative importance with a focus on understanding the reasons for job satisfaction or dissatisfaction. Overall, we referenced journal articles and existing papers on a similar scope to ours. These articles helped us build our literature and knowledge about our problem and gave us insight into counter-arguments and alternative results that we were expecting.

Via logistic regression, I tested the hypothesis using wanting to change current job to represent job satisfaction as the dependent variable and bonuses and services as cash remuneration, residence facility, food/beverage facilities, transportation facilities, and uniform facilities as independent variables. And using control variables such as working age group, involvement status in a job, highest education level attended, and working in the agriculture sector or not. Shortly, talking about the result, there were two models.

The overall results support my hypothesis, where cash remuneration, transportation facility, and uniform facility have shown a significant relationship with job satisfaction. After the regression,

the marginal effect was used to see which variable has a larger influence on job satisfaction. As per the result, received cash remuneration has a major positive influence on wanting to change current job but a negative influence on job satisfaction in both the models. Similarly, following uniforms facility has shown a negative influence on wanting to change current jobs and a positive influence on job satisfaction than other independent variables. This proves that in the case of Nepal received cash remuneration and uniform facility are most influential to the job satisfaction variable.

The study provides useful insight into the linkage between job satisfaction and various factors but not the causal relationship. However certain steps could be taken to make the research more substantial and definitive. Future research could benefit from bigger and more diversified datasets which increases the validity and generalizability of the findings. The research can eliminate potential biases and improve the representativeness of the results guaranteed by an evenly distributed sample. For this research, I have used Nepal Labour Force Survey data which is a secondary data source. But to make future research on this topic more concrete and definitive, a dataset that is catered towards the job satisfaction variable could be used so that it could bring out better representative results. Furthermore, choosing a better indicator for job satisfaction can help strengthen the result for this research topic. Also, addressing the effect of unobserved variables which are intrinsic aspects could help the research with a better identifier for the job satisfaction variable.

The findings of this research on the influencing factors on job satisfaction hold significant importance making it a worthwhile endeavor. Employees' well-being and productivity are deeply connected to their level of satisfaction. Satisfied employees tend to be more engaged and motivated, which contributes to enhancing organizational performance and effectiveness. Furthermore, knowing the factors that impact job satisfaction may help in the development of

policies and practices that improve employee retention, lower turnover costs, and nurture a stable and experienced staff. Work satisfaction also has an influence on employees' emotional and physical health, which could result in less stress and better overall well-being. Hence, the findings of this paper could help decision-making at all levels in promoting ethical and socially responsible practices.

Keeping this result in mind, we should take steps towards introducing more subsidies for uniforms and transportation facilities. Furthermore, also keeping in mind that these factors lie under the hygiene factor as per the theoretical model of Herzberg's two-factor theory. Along with these hygiene factors the true booster of job satisfaction which are the intrinsic factors should be taken into consideration. Hence, it is also necessary to conduct more research into the intrinsic factors which affect job satisfaction and how we can better them to make and keep the Nepalese workforce satisfied with their jobs.

Overall, it is understood by now that extrinsic/hygienic factors only help the employee to prevent themselves from job dissatisfaction while intrinsic factors are major factors for influencing employee job satisfaction. Having said that, services and bonuses like receiving cash remuneration, residence, food/beverage, transportation, and uniform facilities given to an employee from an employer should not be ignored. They might be the major influencing factors in job satisfaction but still, they are important to bridge the gap between job dissatisfaction and job satisfaction.
